# TABLE FOR THE CAPACITY OF BINARY COMMUNICATION CHANNELS <br> MINORU SAKAGUCHI 

University of Electro-Communications
(Received August. 30, 1961)

## 1. INTRODUCTION

First we describe the communication channels we shall treat in this paper. The alphabet in which we send words contains just two letters, which we denote by 0,1 . Thus a sent word of length n is a sequence of $n$ letters, which we shall call an $n$-sequence, each letter being a 0 or a 1 . If we send the word $\left(x_{1}, \cdots \cdots, x_{n}\right)$, then the received word is ( $Y_{1}, \cdots \cdots, Y_{n}$ ) where $Y_{1}, \cdots \cdots, Y_{2}$, are independent chance variables, the probability distribution of $Y_{i}$ depending only on the value of $x_{i}$. If there are just two possible values for $Y_{i}$ which we can assume are 0,1 , the channel is called a "binary channel. A binary channel is essentially characterized by a $2 \times 2$ stochastic matrix

$$
\left(\begin{array}{cc}
p_{1} & 1-p_{1}  \tag{1}\\
p_{2} & 1-p_{2}
\end{array}\right), \quad 0 \leqq p_{1}, p_{2} \leqq 1
$$

where $1-p_{1}$ anb $p_{2}$ are "error probabilities" of obtaining output letter $1-j$ when the input letter was $j, j=0,1$, respectively. A code ( $n, N, \lambda$ ) for the channel is a system

$$
\left\{\left(u_{1}, A_{1}\right), \cdots \cdots,\left(u_{N}, A_{N}\right)\right\}
$$

where $u_{1}, \cdots \cdots, u_{N}$ are $n$-sequences, $A_{1}, \cdots \cdots A_{\mathrm{N}}$, are disjoint set of $n$-sequences, and, for $j=1, \cdots \cdots, N$,

$$
p_{r}\left\{\left(Y_{1}, \cdots \cdots, Y_{n}\right) \in A_{j} \mid u_{j}\right\} \geqq 1-\lambda .
$$

The use of such a code is well-known. If the received word is in
$A_{j}$, the receiver assumes that the word $u_{j}$ was actually sent. Then, no matter which of the words $u_{1}, \cdots \cdots, u_{N}$ is sent, the probability that the receiver will be in error is not greater than $\lambda$.

The most remarkable and now fundamental theorem of the information theory is the following :

THEOREM. Let $\varepsilon$ be an arbitrary positive number. For sufficiently large $n$ there exists a code of length

$$
N \geqq 2^{n(C-\varepsilon)},
$$

where $C$ is a constant determined by the channel characteritic.
The number $C$ is called the capacity of the channel. For a binary channel (1) $C$ is given by

$$
\begin{equation*}
C=\max _{\substack{0 \leq \xi_{1}, \xi_{2} \leq 1 \\ \xi_{1}+\xi_{2}=1}} \sum_{i=1}^{2} \xi_{i}\left(p_{i} \log \frac{p_{i}}{\xi_{1} p_{1}+\xi_{2} p_{2}}+\left(1-p_{i}\right) \log \frac{1-p_{i}}{\xi_{1}\left(1-p_{1}\right)+\xi_{2}\left(1-p_{2}\right)}\right) \tag{2}
\end{equation*}
$$

A binary channel is called "symmetric" if $p_{1}+p_{2}=1$. It is easily found that we have, if symmetric,

$$
\begin{equation*}
C=1+p_{1} \log p_{1}+\left(1-p_{1}\right) \log \left(1-p_{1}\right) \tag{3}
\end{equation*}
$$

and the maximizing $\xi_{1}$ is equal to $\frac{1}{2}$. The numerical table of the expression (3) was first given by Dolanký-Dolanský [1]. The purpose of the present paper is to give a table of numerical values of (2) for general binary channels (1).

## 2. THE OPERATIONS-RESEARCH BACKGROUND

Now, besides its interest of somewhat mathematical nature the capacity (2) of binary cammunication channels has now been given a practical importance in the field of operations research. The author feels at this point some neccessity to remark here that Professor K. Kunisawa of Tokyo Institute of Technology has devoted his efforts in these several years to the exploration of applicabilities of the information theory to various operation research problems.

Several case-studies of considerable interest are reported in his book [2], but they are not completely analysed theoretically. The present author proved in a previous paper [4] a theorem stated below which will throw light on the aspects as Prof. Kunisawa viewed.

Let ( $p_{i j} \mid i, j=1, \cdots \cdots, n$ ) be a stochastic matrix representing the
characteristic of a communication channel with the same sizes of both input and output alphabets. Consider a person who observes the output number $j$. He does not know the input probabilities $\left\{\xi_{i}\right\}$. Hence, of course, he does not know the output probability distribution $\{p(j)\}$, even if he has full knowledge of the channel characteristic ( $\boldsymbol{p}_{i j}$ ). Given the channel characteristic, he can compute the corresponding output probabilities $p(j)$ if he assumes an input probability distribution $\left\{\xi_{t}\right\}$.

Suppose that if he observes the output number $j$ there occurs a gain for him which is equal to the amount $\log p(j)$ of information available and a cost which is given by a real number $X_{j}$. Thus, when the output probabilities are $p(j)$, of which he is ignorant, his expected net gain will be

$$
\begin{equation*}
\sum_{j=1}^{n} p(j)\left(-\log p(j)-X_{j}\right) . \tag{4}
\end{equation*}
$$

Let the numbers $X_{j}(j=1, \cdots \cdots, n)$ representing costs be taken such that if an input number $i$ is selected, there results at the output an expected amount of cost $H_{i} \equiv-\sum_{j=1}^{n} p_{i j} \log p_{i j}$. Or equivalently, $\left\{X_{j}\right\}$ are given by

$$
\left(\boldsymbol{p}_{i j}\right)\left[\begin{array}{c}
X_{1}  \tag{5}\\
\vdots \\
\vdots \\
\dot{X}_{n}
\end{array}\right]=\left[\begin{array}{c}
H_{1} \\
\vdots \\
\vdots \\
\dot{H}_{n}
\end{array}\right] .
$$

The amount of information transmitted per symbol by the channel equals

$$
\begin{equation*}
\sum_{i, j=1}^{n} \xi_{i} p_{i j} \log \left(p_{i j} / \sum_{i=1}^{n} \xi_{i} p_{i j}\right) \tag{6}
\end{equation*}
$$

if the input probabilities are $\left\{\xi_{t}\right\}$. Let us call the maximizing probability vector $\xi^{*}$ of the expression (6) the matching input-probabilities to the channel, and let us call the probability vector $\left\{\sum_{i=1}^{n} \xi_{i}{ }^{*} p_{i j}\right\}$ the matching output-probabilities to the channel. Similarly we shall call the maximizing probabilities $\left\{p^{*}(j)\right\}$ of the expression (4) the matching probabilities to the costs $\left\{X_{j}\right\}$. Then we have a theorem [4] as follows:

THEOREM Let $\left(p_{i j}\right)$ be non-singular, and suppose that there exists a probability vector $\xi^{*}$ such that

$$
\sum_{i=1}^{n} \xi_{t} * p_{i j}=e^{-x_{j}}\left(\sum_{j=1}^{n} e^{-x_{j}}\right)^{-1} \quad(j=1, \cdots \cdots, n)
$$

and $\xi_{i}{ }^{*}>0(i=1, \cdots \cdots, n)$, where $X_{j}$ 's are defined by (5). Then the matching probabilities to the costs $\left\{X_{j}\right\}$ defined by (5) equal the matching output-probabilities to the channel ( $p_{i j}$ ). Moreover the maximum expected net gain when we consider the costs $\left\{X_{j}\right\}$ is equal to the capacity

$$
\max _{\xi} \sum_{i, j=1}^{n} \xi_{i} p_{i j} \log \left(p_{i j} / \sum_{i=1}^{n} \xi_{i} p_{i j}\right)
$$

of the channel ( $p_{i j}$ ).

## 3. THE METHOD AND SOLUTION

The author has given in another paper [3] the solution of our problem (2) as follows. Let $p_{1} \neq p_{2}$, and let $\xi_{1}{ }^{*}, \xi_{2} *$ be the maximizing probabilities. We solve simultanious equations

$$
\left\{\begin{array}{l}
p_{1} X_{1}+\left(1-p_{1}\right) X_{2}=H_{1} \\
p_{2} X_{1}+\left(1-p_{2}\right) X_{2}=H_{2}
\end{array}\right.
$$

where $H_{i} \equiv-p_{i} \log _{2} p_{i}-\left(1-p_{i}\right) \log _{2}\left(1-p_{i}\right)(i=1,2)$ and

$$
\left\{\begin{array}{l}
p_{1} \xi_{1} *+p_{2} \xi_{2} *=2^{-x_{1}}\left(2^{-X_{1}}+2^{-x_{1}}\right)^{-1} \\
\xi_{1}^{*}+\xi_{2}^{*}=1
\end{array}\right.
$$

We obtain from each of these

$$
X_{1}=\frac{\left(1-p_{2}\right) H_{1}-\left(1-p_{1}\right) H_{2}}{p_{1}-p_{2}}, \quad X_{2}=\frac{-p_{2} H_{1}+p_{1} H_{2}}{p_{1}-p_{2}}
$$

and

$$
\xi_{1}^{*}=\left(\frac{2^{-x_{1}}}{2^{-x_{1}}+2^{-x_{t}}}-p_{2}\right) /\left(p_{1}-p_{2}\right), \quad \xi_{2}^{*}=\left(\frac{2^{-x_{2}}}{2^{-x_{1}}+2^{-x_{t}}}-\left(1-p_{1}\right)\right) /\left(p_{1}-p_{2}\right)
$$

respectively. We then have $C=\log _{2}$ $\left(2^{-X_{1}}+2^{-X_{i}}\right)$.

A binary channel can be represented by a point in the unit square as in Fig. 1. By symmetry in the maxim and of (2) it is easily seen that four channels $\left(p_{1}, p_{2}\right),\left(p_{2}, p_{1}\right)\left(1-p_{1}\right.$, $\left.1-p_{2}\right)$ and ( $1-p_{2}, 1-p_{1}$ ), each located symmetrically with respect to the diagonals of the square, are equivalent, i. e., have the same values of the capacity. Thus we are only to compute the values in the shaded triangle in

Fig. 1. The equivalence of the four channels

Fig. 1. The five-decimal-place table on page 60-66 gives the values of $\xi_{1}{ }^{*}$ and $C$ for $p_{1}=0.01,0.02(0.02) 0.48$ and $p_{2}=0.01,0.02(0.02) 1.00$. The computations were performed by the electronic computer HITAC 101.
